## Breadcrumbs

## CURRENT IMPLEMENTATION

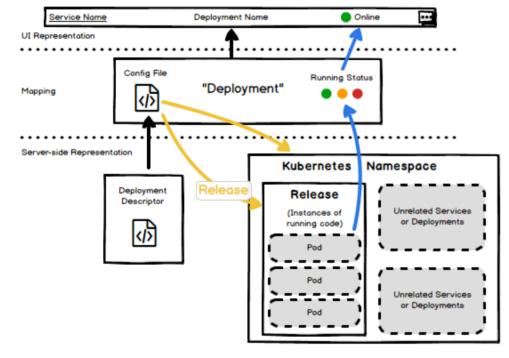

If we have a Release Name and a Namespace, we know that a service is 'deployed'. It may not have any running pods, but space is "reserved" for it.

If a "back door" was used to deploy, we won't have a deployment descriptor NAME (the "template name" for the deployment configuration), but we will have a deployment descriptor (the configuration itself)

It is also possible for a Service to be undeployed, but have a deployment descriptor attached. (essentially there is a config file ready to be used for deployment, but no space has been "reserved" on the namespace, and no "instances" are running)

## PROPOSAL

A service has zero or more 'deployments'.

A "Deployment" is a grouping a config file ("deployment descriptor" which controls release name and namespace) and all running instances

A "Deployment" can have it's config file changed, replaced, or removed.

A "Deployment" can be 'active' (deployed) or a 'draft' (undeployed)

A "Deployment" exists independently of whether it's 'active' (deployed) or whether it has a config file (deployment descriptor)

A "Deployment" cannot be deployed without a config file (deployment descriptor)
